

FIRST RUN

Get started with Athanor

Choose a Wizard build, run a repeatable course, and keep results and evidence together.

Before you start

Use an Apple silicon Mac with Node.js 24+ and local FFmpeg/FFprobe. Foreground checks need an unlocked, available Mac and the relevant existing macOS permissions. Speech checks need the pinned offline model. Your agent can inspect these inputs.

1. Open Athanor

Download

Extract a supplied Athanor bundle and double-click **Install Athanor.command**. Choose your browser on first opening; later use the installed **Open Athanor.command**.

Use your agent

Clone or download Wiz Ops and point your agent at the checkout. Ask it to read **AGENTS.md**, validate setup and open Athanor. From **smoke/**, use **npm run open**. No npm packages need installation. Source-only desktop setup needs a matching SDK/compiler.

2. Choose the build and course

In **Run tests**, open **Find a build**. Browse Releases, Nightlies and Tagged builds, or add an exact tag, URL, ZIP or app already on disk. Use **Mine** to find builds containing your PRs.

Full checklist

153 checks, including 137 accepted definitions and 16 qualification candidates. The fresh default includes physical tests; idle measurement is separate.

Accepted-only

All automated checks · 137 checks. Custom courses can combine accepted definitions. Your agent can run a focused selection.

Engine-only

Build engine checks · 57 checks. Uses the packaged headless engine without foreground input.

3. Prepare the selected build

Press **Prepare build**. Follow adapter setup, fixtures/media, package/schema validation, desktop attachment and ready-plan progress. Athanor attaches external tools to a disposable copy of the exact selected package. When **Build ready** appears, you can start. If setup fails, copy the **Repair with your agent** prompt. A changed build, course or run name needs a fresh preparation.

RESULTS AND FOLLOW-UP

See what happened

4. Start checks

Press **Start checks**. Results shows the active check, elapsed time, progress and outcome counts. Keep the service running and the desktop available for foreground checks. Ordinary failed assertions remain recorded while independent checks continue. Missing prerequisites block their dependent work.

5. Inspect the result

Click a test row to open the right-hand details panel. Read the expected result, method, Operations used, recorded actions and evidence. Clicking another row updates the same panel. Use filters and saved views to focus on the outcomes you need.

Pass	Recorded observations met the check's expected result.
Fail	The check ran and an assertion failed. Review its observation and evidence.
Blocked	A required capability, fixture or prerequisite was unavailable.
Unknown	Execution was interrupted or its outcome could not be established. Inspect before further actions; do not replay an uncertain edit.

6. Keep the report and continue

Open or export the interactive HTML report to revisit its filters and evidence. For follow-up work, copy **Edit this test** or export its agent context pack. Keep the original report when rerunning; each attempt retains its own outcome. Candidate definitions still need lead acceptance before entering custom courses.

Let your agent help

"Set up Athanor from this checkout. Read AGENTS.md, validate the framework and open the local service. Help me choose a build and course, prepare that build, then run my selection and return the report with failures and missing prerequisites."

For agents and test authors

From **smoke/**, run **npm test**, **npm run scope:check** and **npm run open -- --no-open**. Use the printed URL with **--server URL**. Read **docs/test-evidence.md** for reusable fixture/action/assertion/evidence examples. The same adapters support scripted checks and agent-driven spot testing.

Runtime data stays outside Git under the user's WizardSmoke workspace. Fresh is the available starting fixture. Story-user, Large, NAS and the fuller human-handoff workflow are future work.
