

FIRST RUN

Get started with Athanor

Choose a Wizard build, run a repeatable course, and keep the results and evidence together.

Before you start

Use an Apple silicon Mac with Node.js 24+ and local FFmpeg/FFprobe. Full desktop courses need an unlocked Mac and the relevant macOS permissions. Speech checks also need the pinned offline model; your agent can inspect the required inputs.

1. Open Athanor

Download

Open the [pilot release](#), download **Athanor-r10.zip**, and extract it. Double-click **Install Athanor.command**. Choose your browser on first opening; later use **Open Athanor.command**.

Use your agent

Clone [Wiz Ops](#), branch [WIZ-423-smoke-foundation](#) and point your agent at the checkout. Ask it to read **AGENTS.md**, validate setup, and open Athanor. Source-only desktop setup needs a matching Qt SDK.

2. Choose the build and course

In **Run tests**, open **Find a build**. Browse Releases, Nightlies and Tagged builds, or add an exact tag, URL, ZIP or app already on disk. Use **Mine** to find builds containing your PRs.

Start with **Build engine checks** for 57 checks. **All automated checks** selects 137 accepted checks: 57 engine, 73 desktop and 7 services. Give the run a name if useful. Your agent can also compose a course from accepted checks.

3. Prepare the selected build

Press **Prepare build**. Follow the five steps: adapter setup, fixtures and media, package/schema validation, desktop attachment, and the ready plan. Athanor uses a disposable copy of the selected Wizard package and attaches external test tools.

When **Build ready** appears, you can start. If setup fails, open **Repair with your agent** and copy its prompt. Changing the build, course or run name requires a new preparation.

RUN AND REVIEW

From ready to report

Users and agents run the same checks through the same local service.

4. Start checks and watch Results

Press **Start checks**. Results shows the active check, elapsed time, progress and outcome counts. Keep the service running and the desktop unlocked for foreground checks. A failed check is retained while independent checks continue; unavailable prerequisites can block dependent work.

5. Inspect the result

Click any test row to open its details in the right sidebar. Read the expected result, how the test works, **Operations used**, recorded actions and collected evidence. Select another row to update the same panel. Use the table filters and saved views to focus on what needs attention.

Pass	The recorded observations met this check's expected result.
Fail	The check ran and an assertion failed. Review its observation and evidence.
Blocked	A required capability, fixture or prerequisite was unavailable.
Unknown	Execution was interrupted or its outcome could not be established.

Open or export the **interactive HTML report** to revisit the run, its filters and evidence. For follow-up work, copy the test's agent edit prompt. Keep the original report when you rerun; each attempt has its own record.

Let your agent help

"Set up Athanor from this checkout. Read AGENTS.md, validate the framework, and open the local service. Help me choose a build and course, prepare that build, then run my selection and return the report with failures and missing prerequisites."

For source setup, run these one at a time from **smoke/**:

1. npm test **2.** npm run scope:check **3.** npm run open

No npm dependencies are needed. Agents use the printed URL with **--server URL**. Runtime data stays outside Git in **~/Library/Application Support/WizardSmoke**.
